

Figure 1. TED converts dynamic pathway signals into structured event objects

A. Inputs

TED starts after upstream signal extraction; it does not replace trajectory or scoring tools.

B. What TED adds beyond a pathway score

A score can show that a module changed.
**An event object records what kind of event it is,
which artifacts were checked, and which interpretation is supported.**

C. Gate decision path

event-FDR	$q_e \leq 0.10$	pass
block robustness	$S_e \geq 0.80$	pass
negative controls	$M_e > 0$	pass
matched validation	rescue absent	blocked

CB(e) = max tier t such that all required gates pass

D. Why it helps biological claims

TED formalizes the event-interpretation step:

dynamic signal -> event mode -> artifact audit -> evidence boundary

This is the event-interpretation layer missing from pathway scores alone.
